# Results of a Pilot Randomized Trial of a Group Intervention to Reduce Self-Stigma in Veterans with PTSD

# Introduction

- Concerns about stigma and self-stigma can pose significant barriers to the recovery among Veterans with Posttraumatic Stress Disorder (PTSD). Yet, to date, there are no empirically tested, evidence-based interventions to minimize the negative effects of stigma and self-stigma for such Veterans.
- Using information obtained from qualitative interviews, we adapted an existing self-stigma intervention (Ending Self-Stigma) for use with Veterans with PTSD (Ending Self-Stigma for PTSD; ESS-P)
- A pilot randomized trial was conducted to examine feasibility, acceptability, and preliminary efficacy of ESS-P in reducing self-stigma and improving sense of belonging and perceived recovery in Veterans with PTSD.

# **Ending Self-Stigma for PTSD Intervention**

- ESS-P is a 9-session group intervention that aims to help Veterans with PTSD learn tools and strategies to address stigma and self-stigma.
- Group sessions of 6-8 Veterans are held once a week for approximately 75-90 minutes. Each session introduces and practices a new strategy to help group members address self-stigma.

**ESS-P** Sessions

- 1: Introduction to Stigma and Internalized Stigma
- 2: Cognitive-Behavioral Strategies, the 3 C's, Part 1
- **3:** Cognitive-Behavioral Strategies, the 3C's, Part 2
- 4: Strengthening and Diversifying One's Self-Concept
- 5: Increasing Connection and Belonging, Reducing Alienation
- 6: Increasing Belonging with Family and Friends
- 7: Responding to Stigma-based Discrimination
- 8: Course Review
- 9: Crafting Your Own Next steps

## Methods

### **Participants**

- Participants were 57 Veterans with a diagnosis of PTSD receiving VA outpatient mental health services.
- Participants were mostly male (95%), identified as African-American (49%), and were not currently in a relationship (80%).
- Mean age of participants was 53.6<u>+</u>11.0 years
- Mean years of education was 14.2<u>+</u>2.3

### Procedures

- Participants completed baseline and post-treatment assessments lasting approximately one hour that measured clinical symptoms (PTSD and depression), self-stigma, recovery, and sense of belonging.
- Upon completion of the baseline assessment, participants were randomly assigned to ESS-P or enhance treatment as usual (eTAU; written materials on stigma and self-stigma)
- Chart reviews were conducted for the 3 month prior to and 3 months after participation to assess participation in mental health services.

### **Feasibility and Acceptability**

- acceptable.

### **Preliminary Efficacy**

- 2.55 <u>+</u> .54 at baseline,
- utilization.

- with PTSD.
- suicide risk,).
- with PTSD.

### Results

Of those that were approached 90% (63/70) agreed to participate and 81% (57/70) consented.

ESS-P participants attended a mean of 4.10<u>+</u>3.26 sessions; 86% attended at least one session.

Feedback from focus groups conducted after each ESS-P group indicated that participants found the group enjoyable,

informative, and supportive and the content and format

• On average, participants reported a mean ISMI total score of

• There was a significantly greater decrease in self-stigma (ES=-.081) and depression (ES=-0.76) and a significantly greater increase in general (ES=0.81) and social self-efficacy (ES=0.61) and psychological sense of belonging (ES=0.46) among ESS-P participants from baseline to post-treatment compared to control condition participants.

There were no significant differences between groups in changes in recovery, PTSD symptoms or in mental health treatment

# **Summary and Conclusions**

• On average, Veterans experienced moderate to high levels of self-stigma, suggesting the need for intervention.

• Greater declines in self-stigma among ESS-P participants appears to be driven by reduced feelings of alienation and social withdrawal. This coupled with increased sense of belonging and self-efficacy regarding social relationships/ interactions suggests that ESS-P may be particularly helpful in addressing aspects of self-stigma related to interpersonal functioning and relationships, often disrupted in Veterans

• ESS-P may be particularly helpful in reducing symptoms of depression, a common co-occurring condition among Veterans with PTSD which can have additive negative effects (e.g. poorer physical functioning, greater anger/aggression,

 Taken together, our results provide preliminary evidence for the benefits of ESS-P as an adjuvant intervention for Veterans
